# IMPROVING ACCESS TO LEGAL INFORMATION:

# A DYNAMIC THESAURUS TO THE CANADIAN PATENT REPORTER

## SUMMARY

Computer aided information retrieval is based primarily on the matching of words, rather than concepts, a restriction which leads to low recall of relevant items. The problem is particularly serious in legal information systems, where arguments tend to be based on ideas, not just words.

Concepts, typically, are described by a variety of terminology. A way of enhancing word-based retrieval is to provide the searcher with additional terminology for a particular concept by means of a thesaurus.

The Tague/Rees-Potter hypothesis is that the highly cited items of a discipline are concept markers, and that, therefore, the citation contexts of these items are a source of terminology describing the concept, terminology which does not appear in the original indexing of the item and which can be added to a thesaurus.

In the present research, this hypothesis was examined in developing a thesaurus for the Canadian Patent Reporter, 1977-87. The database was installed on a microcomputer hard disk, and the citation identification, context location, and thesaurus development software modules of the software converted to a microcomputer environment.

The 22 most highly-cited cases in the database were used as concept markers and a sample of 10 citing cases selected for each. Terms and phrases were extracted from the database for 22 thesaural groups.

The initial thesaural groups contained many common terms. As a result, a similarity coefficient was determined for each pair of groups. It was found that similar groups tended to be generated by highly cited cases which were frequently cocited in the same case and even the same context. A clustering algorithm merged

similar thesaural groups and developed hierarchical relationships among the groups.

All but four of the thesaural groups and their generating highly cited cases are concerned with opposition to trade mark applications. The concepts which each of these groups represent are not clearly defined, but it is possible to discern some distinctions. Concepts are clearly distinguishable in the groups not concerned with trade marks opposition.

The Tague/Rees-Potter hypothesis was confirmed by the study in that 60% of the terminology provided by the citation contexts was not found in the headnotes of the original cited cases. In the next phase of the study, retrieval tests in a hypertext-based environment will determine the value of this additional terminology.

# IMPROVING ACCESS TO LEGAL INFORMATION: A DYNAMIC THESAURUS TO THE CANADIAN PATENT REPORTER

Traditionally, legal information has been distributed in printed form and searched by means of subject headings supplied by human indexers. Many of the sources of legal information which were formerly published in printed form and searched manually are now available in computerized format. Computer-assisted legal research began in the seventies with LEXIS in the United States and Q/L in Canada. Many predicted initially that the ability of the computers to retrieve every occurrence of a word or other string in a database would revolutionalize legal research, or at least greatly improve results.

However, recent results suggest this prediction is premature. Blair and Maron (1985) showed that retrieval of legal materials based on free keyword searching is unsatisfactory. In an evaluation of a 350,000 page litigation support database, they found that recall, or the percent of relevant material retrieved, averaged only 20%. On the other hand, precision, the percent of retrieved material which was relevant, averaged 79%. Thus, much useful material is being missed, though what is retrieved has a good chance of being relevant.

One problem with free-text searching is the lack of terminological control. Language, particularly when taken out of context , tends to be imprecise and ambiguous. In theory, these problems can be eliminated by human indexers, assigning subject headings from a controlled list. Dabney (1986) investigated the WESTLAW case law databases, which include subject headings and synopses produced by human indexers, and concluded these features improve recall by only a modest amount, about 10%. He found much of the language of these added components very similar to the language in the text of the case.

Ideally, searchers want to search for ideas, not just words. However, ideas must be expressed in words and relationships among words and the same idea can be expressed in many different words.

A single indexer may think of one way of expressing an idea in words; however, a searcher may think of a completely different way. Thus, relevant items indexed by or containing the indexer's words but not the searchers will be missed, and low recall will result.

One way of solving this problem is by using a thesaurus, a listing of terms and their associative and hierarchical relationships. As Kleinbart has pointed out, a thesaurus has value only when it is linked to a corpus of literature, for which it serves as an intermediary between the information available in the literature and the information demanded by the user. The thesaurus functions as a kind of transfer mechanism, providing a specific order to a chaos of terms in the literature.

More specifically, a thesaurus may contain some or all terms and unitary phrases in the database, controlled vocabulary terms and phrases (used) and cross-references to these from other terms and phrases (not used), indications of terms or phrases related to a given term or phrase, and indications of the type of relationship. The development of a thesaurus requires decisions about the source of the vocabulary which it will contain, the kinds of relationships which will be described between vocabulary items, and the procedure which will be used to keep the thesaurus up-to-date.

Initially, vocabulary are derived by specialists from the text units (papers, reports, statutes, cases, etc.) in the database which the thesaurus will describe. Often, particular parts of the text units receive more attention in this selection process: titles, summaries, initial and final sections. The specialists may add vocabulary which is not in the text but which, in their judgment, should be included for a complete description of the items in the database. Thesaurus vocabulary may also be derived by automated means from the texts. Automatic extraction of vocabulary usually involves the removal of stop words, stemming of text words, calculation of word frequencies, and use of the frequencies in deciding which words will be used in the thesaurus.

An alternative approach in legal information retrieval to subject searching is citation searching, i.e., retrieving all items which cite a given relevant item. Usually, though, citation indexing and searching are operations separate and distinct from subject indexing or computer-based string searching. However, recently, there have been some attempts to integrate the two in other disciplines.

Tague (1985) and Rees-Potter (1987) developed the hypothesis that useful additional terminology for describing concepts in a thesaurus can be extracted from the contexts of citations to highly cited papers in a discipline. In their first study, the hypothesis was confirmed using citing contexts of highly-cited papers in economics and sociology as a source of vocabulary for a thesaurus. Citation contexts have an advantage over other sources, as they are not fixed in time and hence provide a means of introducing new terminology and relating it to older terminology. Kleinbart calls a thesaurus a metalinguistic network; it is a metalanguage, a language for talking about language units, i.e., texts. Citation contexts are also metalinguistic entities describing texts, i.e., the cited texts.

The Tague/Rees-Potter hypothesis is based upon that of Small (1980) that highly cited texts in a discipline are concept markers, i.e., represent important ideas. As ideas, they may be described by terms and relationships in a variety of ways, from a variety of perspectives. Citation contexts provide some of these different perspectives. Thus, citation contexts may provide terms not found in the text itself or among assigned subject headings to describe the concept. Over time, the words used to describe a concept will change--calculating machines become computers become information technology. The contexts will track this evolution.

Description of concepts is particularly difficult in the legal field. Dabney points out that the most difficult problem for full-text systems is that much of the meaning of natural language texts is contained in complex relationships between words rather than in

the individual words themselves. Specific points of law may frequently involve very common words--trial, jury, evidence, defendant, plaintiff--with the meaning tied up in relationships among the words, meaning which is not understood by the computer.

In most thesauri, only three kinds of lexical relationships are distinguished: for two terms or phrases **a** and **b**, **a** may be related to, broader than, or narrower than **b**. However, more extended sets of relationships have been suggested. Tague (1981) distinguished two kinds of relationships between terms used to index a set of periodical articles: permanent and transitory. Within the first category, terms were further classified as follows:

morphological variants
synonyms and near synonyms
binary opposition
nonbinary contrast
subordination and superordination
part-whole
entity and an associated process
entity and an associated entity
entity and an associated person

An even more extensive classification can be found in Fox(1980), who distinguished 73 lexical relationships, classed in 11 groups.

Term relationships, like the vocabulary itself, may be determined by a specialist or by automated means, for example by clustering algorithms. The product, the thesaurus itself, may be in printed or computer-based form. However, the latter are more convenient to update; thus, the concept of a dynamic thesaurus, incorporating changing terminology and relationships, is best considered in connection with a totally automated information system.

The important concepts represented by the highly cited items may themselves be related. Highly co-cited items (i.e., cited

together by the same item) may be synonymous or related in some other way. Examination of terminology extracted from citation and cocitation contexts may indicate what this relationship is.

The initial result of applying the Tague/Rees-Potter procedure is a collection of thesaural groups, sets of terms extracted from citation contexts for the same highly cited documents. Sometimes these sets are very similar. In these cases, an attempt is made to determine if there is a cocitation relationship between the two originating cited items. Two modifications of the original collection are then possible:

> If the two sets are identical or nearly identical, it is assumed the concepts represented by the sets are synonymous and they are combined.
>
> If one set (A) is included within the other (B), B is assumed to represent a more specific concept than A. Common terms are removed from B and hierarchical relationships are indicated: B is a specialization of (narrower than) A; A is a generalization of (broader than) B.

In summary, the Tague/Rees-Potter hypothesis is that citation contexts can be used as a source of both terms and term linkages. Highly cited items represent concepts or ideas and the contexts of their citation in other, citing, items a source of the terminology which has been used, in the discipline, to describe these concepts. The fact that terms appear together in these citation contexts means that the terms are related in some way. Thesaural groups made up of these related terms represent major concepts in the discipline. If thesaural groups have terms in common, the concepts each represents are related.

The hypothesis was, in part, validated by the earlier study and programs were developed which would aid a thesaurus designer in extracting terms from citation contexts. However, a full-scale test was not possible within the resources available for that

study. For the same reason, it was not possible in the earlier study, to develop a truly user-friendly, microcomputer version of the database and accompanying thesaurus.

## OBJECTIVES OF THE RESEARCH

The primary objective of the research reported here is to determine if the Tague/Rees-Potter hypothesis can be applied using a case law database. It is the initial phase of a project to develop a microcomputer/CD-ROM based retrieval system for this database, a system which will include a hypertext interface to the database itself and the thesaurus creation and management module.

More specifically, the objectives are:

1. To adapt the Dynamic Thesaurus Creation and Management Software System (Dynamic Thesaurus)to a microcomputer/CD-ROM environment.
2. To study the viability and the effectiveness of this system in developing a thesaurus to the case reports in the Canadian Patent Reporter.
3. To compare the terminology in the subject-heading (headnote) segment of the Canadian Patent Reporter record for a highly cited case to that extracted from the contexts of citations to the case in the summary segment.
4. To determine relationships among the thesaural groups extracted from the citation contexts.

## METHODOLOGY

### Hardware/Software Development

In its initial form, the Dynamic Thesaurus software was written in COBOL and ran on the Decsystem 10 at the University of Western Ontario. The Canadian Patent Reporter for the period 1977-87 was donated by Canada Law Book in magnetic tape form. It contained a total of 3,052 cases. In order to develop a microcomputer-based thesaurus for this database, a number of decisions had to be made regarding the hardware and software environment.

The three modules which formed the original Dynamic Thesaurus System were converted using the C programming language and Windows software so that they now run on an IBM/AT compatible microcomputer. These modules are:

1. A citation identification module which, given the identifier of a highly cited item (case), searches the database for all citations to the item.
2. A context identification module which finds the location of the actual citation within the text and displays the context.
3. A thesaurus maintenance module which permits the thesaurus manager to input the terms and phrases for thesaural groups.

Appendix 1 shows a typical session with the thesaurus maintenance module.

Several options for storage of the Canadian Patent Reporter database were investigated and compared from the point of view of accessibility and cost, including commercial CD-ROM, a WORM drive, and a 100 MG hard disk. In the end, the hard disk form was selected for both the database and the thesaurus as being the most flexible for development of the entire retrieval system. Once development is complete, the database will be transferred to CD-ROM; however, the thesaurus will remain on hard disk, to permit

continued updating. The conversion of the database from magnetic tape to hard disk proved to be more difficult to achieve than had originally been anticipated, and led to delays in completion of the project.

**Thesaurus Development**

The first step in the development of a thesaurus based on the Tague/Rees-Potter hypothesis was the determination of the highly cited cases using the citation identification module of the Dynamic Thesaurus. The frequency of citation in the Canadian Patent Reporter (CPR), 1977-87, of all cited CPR cases is shown in Appendix 2.1, in order of decreasing frequency. Citations of cases in other reporters or of statutes were not included, in order to limit the scope of the study to a reasonable size. A later investigation of these omitted citations may be undertaken. Appendix 2.2 provides a table giving the frequency distribution of citations.

The second step in the development of the thesaurus is the examination of the citation contexts of highly cited cases to determine appropriate words and phrases to include within the thesaural group for the concept represented by the highly cited case. Here, several decisions had to be made. First of all, a citation context had to be defined. O'Connor has suggested a sophisticated algorithm for determining the context of a literature citation. However, examination of the case law reports led to the conclusion that this algorithm would not be appropriate, because of the nature of argument presentation in the reports.

It was decided to use the paragraph in which a citation occurred as its context, with two exceptions. Citations occurring in a paragraph or series of paragraphs headed by the phrases "Cases Referred To", was ignored, since the paragraph here is a simple listing and, usually, the case would be cited again in a paragraph which indicated its relationship to the arguments being presented. In the other exception, more than the paragraph was considered if

the context paragraph or the preceding one ended with a connecting phrase such as "as follows:" or "stated:".

The next decision related to the number of highly cited cases to be considered and the number of citation contexts to examine for each. For the test, the 22 cases in the Canadian Patent Reporter which received 60 or more citations were used as concept markers for the initial thesaural groups and a random sample of 10 contexts were examined for terminology for each of these. Time limitations precluded further analysis, but it is intended, in the continuation of the project, to include additional highly cited cases, perhaps including all those with 20 or more citations.

The citation identification and style of cause and the CPR number of the citing cases examined for each highly cited case are shown in Appendix 3.

The investigator selected those strings in the context which seemed salient to the citation of the highly cited case. Most extracted strings were individual words converted to a nominal form. However, in some cases, closely related adjective-noun phrases were included, together with the noun separately. Counts were made of the number of times each word or phrase occurred in the citation contexts for a particular highly cited paper.

As in the earlier studies of Tague and Rees-Potter, selection of the words and phrases from the contexts was somewhat subjective. Only content words were selected, not function words. Selected words were converted to nominal form; where an adjective seemed significant and could not be converted to a noun form (e.g., dominant feature), the entire phrase was retained. However, most of these guidelines could be algorithmatized.

Appendix 4 shows the terminology and associated counts for the initial thesaural groups. Appendix 5 contains an alphabetical list of all strings extracted from the contexts, with total number of times the string appeared in all contexts in all thesaural groups.

In the Canadian Patent Reporter, as in most case law reports, indexing is provided by a string of phrases (descriptors) at the

beginning of the headnotes, which themselves are summaries of the full reports. A reasonable question to raise about the Tague/Rees-Potter hypothesis is whether the contexts provide any additional terminology beyond that already to be found in the headnotes of the cited case.

Whether or not each string in the thesaural groups is in the headnotes for the highly cited case which identifies the group is indicated in Appendix 4 by a 'Y' or 'N' at the end of the entry for each string. Unfortunately, it was not possible to obtain copies of three of the highly cited cases (4 C.P.R. 48, 5 C.P.R. 71, 10 C.P.R. 101). Overall, omitting the three missing highly cited cases, 36.2% of the strings extracted from the contexts matched strings in the headnotes; thus, 63.8% of the strings represented new entries for the thesaural group.

Examination of the initial thesaural groups in Appendix 4 shows similarities among some of the groups. In fact, some groups contain all of the terminology of others. To investigate these similarities further, the cosine measure of association R(X,Y) was calculated for each pair of groups X and Y, as follows:

$$R(X,Y) = X_i Y_i / X_i^2 \; Y_i^2$$

where $X_i$ is the weight assigned to the ith string in group X and $Y_i$ is the weight assigned to it in group Y. The weight of a string in a group is the number of contexts for that group in which it appears divided by the total number of contexts in which it appears.

Cosine values vary between 0 (when two groups have no terms in common) and 1 (when two groups are identical). No pairs of groups had cosine similarity values of 1; 28 pairs had cosine similarity values greater than 0.1. These are listed in the table in Appendix 6.

It was hypothesized that pairs of groups which showed high similarity would correspond to pairs of highly cited cases which

were frequently cocited in the same case, perhaps even in the same paragraph. The last two columns of the table in Appendix 6 show the proportion of the citing cases for the two highly cited cases which cited both cases. The fourth column represents the proportion which were cocited within the same case; the fifth column the proportion within the same context (paragraph). The correlation between the terminological similarity of the two groups, based on the cosine measure, and the proportion of cocitations of the two highly cited cases which generated the groups is 79% for cocitations within the same case and 70% for cocitations within the same context.

Examination of the initial set of thesaural groups thus revealed that some groups were very similar and so represented similar or related concepts. In order to represent these relationships in the thesaurus, the original thesaural groups of terms were organized or hierarchically clustered using the following procedure:

1. The procedure began with the original set of 22 thesaural groups of terms as clusters.
2. All pairs of thesaural groups with similarity coefficient greater than 0.1 were merged into a single cluster by forming the union of their term lists.
3. All cluster pairs were compared.
   - 3.1 If clusters had identical term lists or differed by no more than two terms, they were merged;
   - 3.2 If the term list of one cluster was totally contained within the term list of another, a specialization ('narrower than') relationship was indicated from the latter to the former and a generalization ('broader than') relationship from the former to the latter. Common terms were eliminated from the more specialized list.
4. Step 3 was iterated until no additional merging occurred.

The clustering structure is indicated in the Figure in Appendix 7. Appendix 8 gives the revised thesaurus, with the thesaural group relationships indicated.

Weights for strings in the revised groups were calculated in the same way as in the original groups, i.e., number of times the string occurred in contexts for the group highly-cited documents (one or more), divided by total number of occurrences of the string in all contexts. Only strings with a weight of at least 0.1 were left in the revised thesaural groups. This decision was made in order to eliminate low-weight terms which appeared in almost all groups, e.g., 'trade marks'.

## DISCUSSION OF RESULTS

Voges (1988) suggests that computer-aided legal research based solely on string searching in full text would retrieve a very precise set of items based on facts rather than concepts. She goes on to say: "This would lead to lawmaking on a very narrow plane, one in which there was a very close match within the facts: lawmaking through analogy would be lost as arguments become more and more reliant on cases or regulations that closely match a fact or particular pattern rather than the general legal concepts as applied to many specific fact patterns."

To what extent does the Tague/Rees-Potter hypothesis mitigate against this tendency to base retrieval on facts rather than concepts?

Eighteen of the twenty-two most highly cited cases in the Canadian Patent Reporter are concerned with opposition to a trade mark application; one with patent infringement, one with the authority of the Federal Court of Canada under the Trade Marks Act, one with the obligations of ex-employees, and one with an alleged error in granting of an interlocutory injunction. Examination of the terminology extracted from the contexts, in Appendix 4, bears

out this emphasis on trade marks. Many of the term lists are similar, with the exception of those generated by cases not involving trade mark opposition directly (8,10,11,14).

As Appendix 6 shows, twenty pairs of groups had highly similar lists (similarity coefficient greater than 0.1). In many cases these represented cases which were often cited in the same case, or even the same paragraph. In a couple of cases [pairs (2,3) and (10,11)] the decision in one of the cases affirmed that in the other. The high correlation between thesaural group term list similarities and cocitations is a partial validation of the Tague/Rees-Potter hypothesis, in that cases with similar citation patterns produce similar term lists and so would seem to represent similar concepts.

The clustering procedure was undertaken to reduce the number of thesaural groups and to develop relationships among the groups. It succeeded to some extent in this endeavor: the number of thesaural groups was reduced from 22 to 19 and 7 inter-group relationships were developed.

Somewhat more distinctive thesaural groups resulted from this procedure, though there are still many resemblances. Groups 1 through 15 relate to trade marks. Some distinctions suggest themselves among these groups, though certainly not in a clear-cut fashion. The concept which appears to be represented by each group is given in the table below:

| Group No. | Concept |
|---|---|
| 1 | extent of use, public recollection of trade mark |
| 2 | distinctiveness of the trade mark |
| 3 | advertising, making trade mark known |
| 4 | judging the similarity of trade marks |
| 5 | evidence of first use of trade mark |
| 6 | basis on which a prior decision re a trade mark can be overturned |
| 7 | significance of time of filing application for trade mark |
| 8 | evidence of first use |

9 geographic extent of use or recognition
10 aspects of the registration process
11 evidence relating to trade mark use and recognition
12,13¦ appearance of the trade mark, use of words, letters
14,15¦ and other symbols

The other concepts are more precisely defined and distinguished:

**Group No. Concept**

16 patent infringement involving a consideration of the meaning of the specification to experts
17 authority of the Federal Court of Canada vs the provinces in issuing injunctions based on a section of the Trade Marks Act
18 former employee taking business advantage of information obtained while employed
19 validity of an interlocutory injunction

The Tague/Rees-Potter hypothesis that citation contexts can be used as a source of both vocabulary and lexical relationships among vocabulary items in a textual databases has been only partially confirmed with the Canadian Patent Reporter. Over sixty percent of the items provided by the contexts were not in the headnotes of the original cited cases, indicating that the contexts were a source of additional vocabulary. However, it is not absolutely clear that there is a stronger relationship among the terms in the thesaural groups generated by the highly-cited cases than among terms in different groups. Clustering improves the distinctiveness of groups somewhat, and some patterns can be detected. Even here, though one hoped for more clear-cut demarcations among the thesaural groups.

An open question is whether a larger sample of either highly cited cases or citing cases for each cited case and the inclusion of highly cited items from other sources would have improved the thesaurus. It is hoped that this extension of the research can be

undertaken in the near future.

## THE NEXT PHASE

Hypertext or nonlinear text provides the capability of perusing text following a variety of links. However, what is not clear, at the present stage of development, is exactly what links and paths (link sequences) need to be implemented in hypertext systems in order to obtain needed information in the most efficient manner. This problem becomes particularly acute in large full-text databases such as the Canadian Patent Reporter.

Links can be characterized as structural (for example, from a later section to the introduction or headnotes), internal information (for example, from a reference or word within the case to the same reference or word elsewhere in the case), and external information or domain (for example, from a reference in the case to the text of the case report itself, or from a word in the text to the thesaural groups in which it occurs).

In the next phase of this research, the question of appropriate links in a hypertext interface to a CD-ROM version of the Canadian Patent Reporter and the Dynamic Thesaurus developed in the present project will be investigated. As a part of the development of this interface, use of the database via a prototype hypertext interface will be studied. Among other information, this use will indicate the value of the Dynamic Thesaurus to improved retrieval.

Specifically, the next stage involves the following steps:

1. Development of a prototype hypertext interface, with the following features:

--browsing via hypertext links

--link types include:

- structural
- internal information
  - citation contexts
  - keyword contexts

external information
cited cases
thesaural groups
--backtracking, return to previous nodes
--string search within case
--thesaurus updating
--printing of sections.

2. Transfer of case database to CD-ROM.
3. Trial use of database and thesaurus by students at UWO Law School, for assignments.
4. Trapping of trial use via transaction logs.
5. Development of mathematical models of user paths in hypertext based on trial data.
6. Determination of additional useful citations obtained in trial via the Dynamic Thesaurus terms and phrases.
7. Based on the trial data and the mathematical models which it suggests, recommendation of optimal file structures for hypertext systems for large text databases.

The Dynamic Thesaurus project has thus been a first step in what should evolve as a truly useful study of the best ways of handling large full-text databases in present-day computer environments.

## ACKNOWLEDGEMENTS

The accomplishment of this project would not have been possible without the skill and perseverance of Judy Steward and Charles McClellan, who developed the computer software and carried out the computer processing for this project.

The generosity of Canada Law Book in donating the Canadian Patent Reporter on magnetic tape to the project is gratefully acknowledged.

This project is an extension of work originally carried out with Lorna Rees-Potter, now of McGill University, Graduate School of Library and Information Studies. Many ideas in the present study resulted from conversations with her.

JUN - 4 1990

The UNIVERSITY of WESTERN ONTARIO
*School of Library and Information Science*

30 May 1990

Ms. Gail S. Dykstra
Senior Director, Policy and Programs
Canadian Law Information Council
600 Eglinton Avenue East, Suite 205
Toronto, Ontario
M4P 1P3

Dear Gail,

Enclosed is a WP5.1 version of my report Improving Access to Legal Information; a Dynamic Thesaurus for The Canadian Patent Reporter.

I would also like to point out an omission in the report which I sent to you. The formula in the middle of page 10 omitted some symbols. The correct form is:

$$R(X,Y) = \sum_i X_i Y_i \; / \; \sqrt{\sum_i X_i^2 Y_i^2}$$

With best wishes,

Jean M. Tague
Dean
